Dedication

This project work was dedicated for my beloved wife Glelele Hailu and my sons Fraol and Hundaol.
Acknowledgements

First and foremost, Glory to God. Without God’s support and guidance in my life, nothing would have been possible. I am also very grateful to my advisors, Dr. Derje Teferi and Dr. Demeke Assefa. They are not only my advisors but they are also my mentor. Thank you for giving me meticulous comments and correction without your comments and correction I may be out of track. Of all the qualities of my advisors, there kindness touched me most. Thanks Dr. Derje and Dr. Demeke you have a place in my future career.

Many thanks go to all staffs of SRH specially Dr. Wahib medical director of the hospital for he has shown me a great respect and hospitality during my project work .In addition, S/r kelamua and S/r Etenesh working in the ward and Ato Jemal who were working in the HMIS office for assisting me in requirement gathering and for giving me your time in responding to my questions. You deserve respect guys!

I know I tend to be a nuisance when things are not going in my way and putting up with this is very difficult. Fortunately, I am blessed with a wonderful wife w/r Gelgale Hailu who has a limitless tolerance to all my agitations. I really appreciate this with lots of love and respect as I always do.

I would also love to thank Abiy Kassa who let me use his office and give me development tools he also deserve equivalent respect with others. Thank you Obama!

Furthermore, many thanks go to my Dad Ami Morke, Mom Alemitu Uka and Youngest sister Bontu Ami for financial support. I really appreciate this with lots of love and respect. I thank God for having you as family.

Finally, my deepest gratitude goes to the all time friend of mine, Pastor Bushura Teshita. I just can’t thank you enough. May God bless you?

Abstract

Background: To provide quality of health care, medical practitioners require complete, accurate, and timely data. Practitioners need to know their patients’ medical history to avoid prescribing treatments that may have adverse effects. Though, most medical records are kept in voluminous paper files, typically located in doctors’ offices or other health service provider sites. These files are often not available when most needed in addition report generation from these files is also difficult and not timely. To overcome this catastrophic problems designing of a patient record system is mandatory

Objective: The proposed project attempted to Design a Patient Record System for Shashemene Referral Hospital which enables the user of the system to use patient data effectively and to pass good decision on patient treatment.

Methodology: The proposed project used Structured System Analysis and Design system development approach and it used different data collection tools i.e. (interview, observation and relevant document review techniques) to collect sufficient data needed for the system to be developed. Analysis and design of the proposed system was performed by using analysis and design technique i.e. Data Flow Diagrams (DFD) for process modeling, Activity Diagram and Entity Relationship Diagrams (ER) for data modeling, for programming language Hypertext Preprocessor (PHP) and Hyper Text Markup Language (HTML) were proposed for implementation phase. Structured Query Language (SQL) server 2008 and Microsoft Access 2007 were the tools used for data base table construction and their relationship. For data flow diagram the tool used was Microsoft Visio 2007.

Result: The developed design of a patient record system for Shashemane Referral Hospital incorporates Register new /update repeat patient detailed information, Search patient detail, assign patients to different case team, manage patient treated at Out Patient Department (OPD), admitted patient, bed schedule, nursing care plan, discharge summary, user account and generate report. To capture all of these data relational data base system was designed. Finally, system architecture also designed to give a high level view of the new system.

Conclusion: Patient health history recording is mandatory it helps the health professionals to easily accesses health history and prevents them from prescribing drugs that has adverse effects which threatens patient’s life. The developed design of a patient record system contains patient registration, management of patient history at Out Patient Department and Inpatient Department and also report generation for stake holders.

Recommendations: To achieve the aim of this project Shashemane Referral Hospital, Addis Ababa University and other stake holders should react on the implementation phase of this design document and a great effort should be made to give training of workers at hospital who participate in management of health information.

CHAPTER ONE

Introduction

Patient record is “a warehouse of information about an individual's lifetime health status and health care, stored electronically or manually” [1]. There are two types of patient record systems which are used to manage patient information, namely paper-based record system and the computer-based record system. The basic advantage of developing computer-based record system is to increases the accessibility and use of the patient record or data. And this is also one of the aims of one country’s Health Information (HIS) System in order to improve the HSD (Health System Development), and the health status of the population [2].

“To provide quality health care, medical practitioners require complete, accurate, and timely data. Practitioners need to know their patients’ medical histories to avoid prescribing treatments that may have adverse effects. They need quick access to the results of laboratory tests and other diagnostic procedures to determine the best treatments. In emergency situations, critical information can mean the difference between life and death. Yet most medical records are kept in voluminous paper files, typically located in doctors’ offices or other provider sites. These files are often not available when most needed. Even hospitals and medical facilities now using automated systems cannot easily access patient data maintained by other providers [3].

“Electronic sharing of medical data offers great potential for improving health care delivery by providing doctors with full knowledge of patients’ medical histories, permitting many practitioners to share a patient’s data simultaneously, and reducing the need for costly duplicate diagnostic tests. Similarly, insurers will be able to increase their efficiency and productivity through electronic claims submission and payment [3]”.

To improve the routine HIS there is a growing recognition that Information Communication Technology (ICT) can replace traditional routine paper-based HIS with flexible electronic means and could bring significant cost reduction and effectiveness in terms of timely delivery of health care services in developing countries [4]. “Electronic systems also maintain quality and accurate data, and make reporting potentially more flexible and efficient. On the contrary, in paper-based systems the data is collected and compiled manually at each site where the data is collected, a process that hinders managers and decision makers at higher levels of the hierarchy from viewing the disaggregated data coming from lower levels of the system [5]”. Besides this, accessibility of data in the paper-based system is time consuming, potentially unreliable and inefficient when the number of records becomes very large [6, 7].
As a solution to such challenges medical databases have been implemented to the health system since 1960s [8]. During their first invention they were used to provide a patient’s billing service. Later on, as Linberg mentioned, these databases were started to use for the purpose of collecting and storing patient’s medical history. Nowadays medical database has different comprehensive functions including CDS, Order entry, electronic information exchange etc [9].

Following the change of government in 1991, the new Government of Ethiopia put in place many political and socio-economic transformation measures. Among these, it developed a first national health policy, which was followed by the formulation of four consecutive phases of comprehensive Health Sector Development Plans (HSDPs), starting from 1996/97. At the core of the health policy are democratization and decentralization of the health care system; developing preventive, promotive and curative components of health care; assurance of accessibility of health care for all parts of the population; and encouraging private and NGO participation in the health sector. HSDP-IV is a policy level strategic document that will guide the development of sub-national plans and set the rules of engagement in the health sector [10].

One of the strategies of health policy of Ethiopia is organizing HMIS (Health Management Information System) by: Managing the system appropriate and relevant for decision making, planning, implementation, monitoring and evolution, maximizing the utilization of information of all levels and developing central and regional information documentation center [11].
1.1. Background

Shashemene Referral Hospital is found in Kuyera town about 238 km south of the capital city Addis Ababa. It is one of the most experienced hospitals of the region with more than 50 yrs of service for the population of the area which is currently estimated to be 2.1 million people. It was built by missionaries in 1942 and in 1968 upgraded to governmental general hospital. In 1999 the hospital upgraded to referral hospital. Now a days the hospital encompasses 12.2 hectares of land with a total of 242 employees (Technical=123, Supportive=242 employees) with the bed number of 167. The hospital on average serves 254 patient per day [12].

The hospital is situated in the West Arsi Zone, Shashamane woreda. This Hospital has been experienced huge growth. Due to the growing number of patients, daily operations have increased to the point that it has become quite difficult for Hospital personnel to manage all paperwork related to Hospital operations. The purpose of this document is to present, in a detailed manner, the requirements needed by Shashemene Referral Hospital (SRH) [12].

The hospital is giving different types of services which include:

**Out Patient Department (OPD) Service Includes:** (Ophthalmology, Dental clinic, Obstetrics and Gynecology, Emergency and ART clinic).

**Inpatient Services Includes:** (Pediatrics ward, Medical ward, surgical ward, Oby/Gyn Ward and TB/Lep.)

**Pharmacy Services Given for:** (Inpatient, OPD and ART patients)

**Investigation departments**

- **Laboratory Service Given for :** (Inpatient, OPD and TB/Lep patients)
- **Radiology(x-ray, Ultrasound)**

**Human Resource Description of Shahemane Referral Hospital**

**Table 1:** Human Resource Distribution

1.2 Statement of the problem
Paper-based patient record management faces many challenges. It decreases quality of information management in health care, and also reduces the productivity and quality of care provided. It does not allow sharing information between different places at the same time. Paper records may be lost, not easily accessible and might not contain full information for decision making or for action. Printing cost for format is also high. It is also not convenient as physicians and other health care providers have limited time to dig through volumes of paper to retrieve information for decision-making and/or share it with patients. It also leads to medical errors in prescriptions, as writing them on paper might not clear and is too difficult to read it [13].

The assessment result done by Angaw S. BraaJ showed that SmartCare also shows it was adopted with immature requirement analysis and recommends for better situational analysis [14].

Through the interview made with Dr. Jemal expert of Public Health Specialist at Tulane University showed that: The current smart care software does not incorporate the updated indicators which necessitate the development of new smart one and TB /Lep treatment outcomes are not fully built-in in the software which shows requirement collection process was not participatory which in turn causes problem in data entry and report generation.

Preliminary study was done at Shashemene Referral Hospital in search of problems in the current system and to identify the felt need of the hospital for new system. According to the response received from Ato Jemal who was working in Medical Record Unit of Shashemene Referral Hospital reviled that the large number of patients visiting the hospital has created cumbersome task to the workers in Medical Record Unit. This enormous task has greatly increased volume of data to be collected, large space to store them and difficulty to retrieve useful information from stored data. In addition, the other observed problem that was mentioned by the respondent was in the current system (i.e. the paper based system) the data entry is prone to error and redundancy of patient medical record frequently occurred.

During assessment of smart care implementation at Ras Desta Hospital by Health Informatics (HI) students of 2013 batch they documented the response of responsible individuals Nurayna and Engdawork: The formats on the smart care software which helps to register treatment outcomes of TB cases were not fully included. For instance, some of the formats uses for TB diagnosis and investigation were missed as well as some formats in the smart care were complex when compared to the HMIS form and the forms are different from the manually registered one this in turn cause difficulty for the users of the soft ware. The other problem detected was TB report format in the software was not put like the manual Unit TB Register which missed the treatment out come. So, they used to report manually.
The other problems found in Smart Care were security issues. The password and user name is the same for one department. Everybody working in that particular department use the same user name and password this leads to difficulty in identifying the person who sent investigation report this situation becomes worse when the reported investigation is found wrong or incomplete and it doesn’t incorporate nursing care plan that is given for admitted patient. Hence, this project is designed to investigate and give solution for the existing system problems which are described above.

1.3 Objective

1.3.1 General objective
To design current manual Patient Record System this was used by Shashemane Referral Hospital.

1.3.2 Specific Objectives
To achieve the general objective, the following specific objectives were stated.

- To elicit system requirement and identify the system’s requirements
- To analyze system requirements
- To design a Patient record system

1.4 Significance of the Study

To students: The proposed System Analysis and Design document serves as the basement for future implementation of software by interested students.

For the Hospital and the Health Centre or other health facility: The new proposed document i.e. analysis and design of a patient record system will help for all health facilities to include the felt need and process of their departments. And also help them to outsource the implementation phase of the proposed project for external entity and meanwhile, to follow the implementation of there need.

For Doctors and other Health professionals: when the proposed well analyzed and designed Patient Record System document deployed one of the users will be health professionals. So, this analysis and design document will help to include all their needs so that the future software will be users friendly.

For Medical research, Statistics and Teaching: The proposed analysis and design document is also valuable to design software that will help in the collection of statistics data on health care/services and the incidence of diseases. Furthermore, the proposed document will help for teaching health informatics students.

For Non Governmental Organization: A System Analysis and design document of a Patient Record System will help NGO’s who are working in the area of health sector
software development as a base document to identify the best programming language to use and to design new software.

1.5 Scope and limitation of the project

The proposed project focused on design of a patient record system for Shashamane Referral Hospital which is found in west Arsi Zone, Shashemene woreda, Kuyera town. In addition, the proposed project also focused on developing system requirement and analysis, design document of the system, which can maintain information about health condition of the patient who was registered at Medical Record Unit and then treated at OPD’s and Inpatient departments of the hospital and to recommend a web based communication between them. A web based communication also help for easy accessibility of the data when ever needed by FMOH, RHB, patients and health professionals. The above mentioned scope of the project was done by the use of structured system analysis and design methodology between February- June, 2014Gc.

Due to limitation time, the proposed project does not include design of specific services of the hospital like Laboratory Information Systeam(LIS) and Pharmacy Information System, which can be networked to Doctors who are working at OPD’s and IPD’s.
CHAPTER TWO

Literature review

2.1 General literature

Information System

According to the definition of O’brien information system encompasses people, hardware, software and communication network that helps to control, transform and distribute information between organizations [15].

According to World Health Organization, WHO, 2004 : Health information System is a system that integrates data collection, processing, reporting and use of information necessary for improving health service effectiveness and efficiency through better management at all levels of health service[15].

Records Management

Records Management is the practice of identifying, classifying, archiving, preserving, and sometimes destroying records according (International Standard Organization, 2001). Defines records as “information created, received, and maintained as evidence and information by an organization or person, in pursuance of legal obligations or in the transaction of business [15]

Push for Medical Computerization

According to Meghan report Electronic Medical Record could save 140 billion dollars a year in health care expenses. While saving tens of thousands of lives each year. The technology dramatically reduces the time between a patient’s initial consultation with a physician and his receiving treatments. Electronic Health Record also dramatically cuts errors in prescribing drugs that can cause severe problem in patient’s life and reduce redundant drug prescriptions [15].

Creation, expansion and linkage of health record system is the aim of health system development. The importance of health record system also includes reduction of medical errors which may leads to improvement of patient safety, helps health professionals to communicate relevant patient health information’s. In addition good health record system reduces cost of the organization, increase efficiency of health organization and reduce duplication of medical records [16].
Heath Information

Health information is recorded information regarding physical or mental condition of an individual, health care provision, or health care payment collected routinely from the health service or periodically from the population [17].

Use of health Information System

The essence of health reform and decentralization of health system describes that health systems should be managed at the level of service delivery. This in turn leads to the shift of functions between the central and peripheral levels which generates new information needs and calls for the restructuring of information systems to collect and use information for decision making at local, district, provincial and national levels [17].

A study done by the WHO clearly put that “the function of HIS is to bring together health data from different sub-systems (sources) to share and disseminate them to the different audiences for health information (owners, providers and users) and to ensure that health information is used rationally, effectively and efficiently to improve health action. Therefore, strengthening the HIS is a core process in using patient data [18].

Through HMIS the routine HIS reporting of information is upward in health system. One of the problems of upward reporting of health information data is poor quality. However it is proved that this poor quality of reported health information can be improved at the local level before sending up as a report. One of the mechanisms to control the quality of data is to make facility members to be local consumers of data. The facility managers monitors its accuracy, completeness (how well it represents the population served), and timeliness (whether the data is fresh enough that decisions taken on its implications are likely to affect the situation) before sending it upwards. When information is utilized and controlled by people who collected it will be more accurate. The improved quality following extensive use of data leads to father assurance to use of data leads to further assurance to use data at all levels of the health system[19,20].

Qualities of a Good Information System

According to Comptroller an information system includes the following [21].

Efficiency: a good information system should allow for input and output by providing an objective for recording and aggregation information. It should be able to quickly collect and edit data, summarize results, and adjust as well as correct errors promptly.

Effectiveness: a good information system should be able to attain its goals or the goals of the organization. To simplify prompt decision making, an organization’s information system should be capable of providing current information to appropriate users.

Performance: A good information system should be able to enhance communication among employees, deliver complex material throughout an organization.

Time lines: Information system should be designed to expedite capturing, storing and reporting information in a real time scale when needed.
**Consistency:** A good information system should be reliable. Data should be processed and compiled with consistency and uniformity. Variations in how data is collected and reported can distort information and trend analysis.

**A Note on Terminology**
The Oxford Textbook of Primary Medical Care describes medical records as “the information that exists about a patient in a medical service”. Record keeping assists doctors by retaining and communicating patient medical history in a portable, convenient format. Relevant information must be quickly available to allow rapid, effective decisions and reduce unnecessary repeat procedures. The natural medium with which to record medical history is paper, since it is simple to use, low in cost, and reasonably durable. Information may be quickly added and readily shared amongst health professionals caring for a patient. However, problems arise due to the decentralized nature of the healthcare system; patients frequently visit different offices for dental work, cardiology, and primary care, impeding the necessary flow of medical information. Fragmented, incomplete patient records pose an obstacle to patient care. An electronic medical records system has the potential to solve the problems of traditional paper records [22].

Generally there is confusion in the definition of Electronic Medical Record and Electronic Health Record. Most people use these words interchangeably this is due to lack of clarity in health sectors, health professionals, policy makers and consultants about these terms; the fact that there is no standardize or accurate or accepted definition. To avoid these confusions the following listed definitions are selected. The selection of these definitions based on their clarity and comprehensiveness. Electronic Medical Record is automated for clinician’s work flow and ensuring that all clinical information is communicated. Electronic Medical Record support physicians in decision support because it incorporate evidence-based decision support system tools. The other main difference between Electronic Medical Record and Electronic Health Record is in case of Electronic Medical Record it contains data that are useful for billing, quality management, outcome reporting and public health surveillance. Moreover, Electronic Medical Record has additional features such as clinical decision support, a provider order entry system, a controlled medical vocabulary or result reporting system, in general terms Electronic Medical Record is a system which helps physicians to enhance their patient management[23].

Electronic Health Record is the system that helps to capture health in formations of the patients including vital sign, immunization, diagnosis, medications, present and past histories, progress notes, laboratory data and radiology report.

A third type of record is Personal Health Record which is controlled and managed by patients it is universally accessible, layperson comprehensible, lifelong tool for management of chronic disease[23].
System Analysis and Design Approach

It is a common approach of software development it passes through SDLC phases. At the completion of each activity or phase, a document is produced that must be approved by the stakeholders before moving to the next activity or phase. The developer will not go back to the former phase even if problem occurs for this reason it has got the name waterfall system [24].

Structured System Analysis and design (SSA/D)

This methodology was dominated in late 1980’s. It’s incorporate SDLC passes in which the development process to go through. In addition this methodology introduces the use of formal modeling and diagram technique. This methodology gives emphases for process modeling and data modeling. For process modeling it will use data flow diagram and for data modeling this approach will use a relational database system [25].

The Object-Oriented Approach

This methodology views the system bottom-up approach. It uses different diagrams to describe functions of the system this diagrams are known UML (Unified Modeling Language.

When Object Oriented Approach used with another methodologies it becomes Unified Process. The Unified Process uses iterative and incremental system development method. These are inception, elaboration, construction and transition [25].

Rapid Application Development Methodology

In weakness of structured System Analysis and Design the Rapid Application Development appeared around 1990’s. This methodology more focus on rapidly developing a system And it adjusts the SDLC phases to get some part of the system developed quickly and into the hands of the users. This can helps the users to understand the features of the system and participate in developing process [25].

Agile Development Methodology

The agile methodology is programmatic centric and it focuses more on building a working software just in time it doesn’t focus on documentation process. in this methodology changing of requirements even at the end of development is tolerable[25].
2.2 Related Works

A study that was done by Hiwot that attempt to develop patient record system for Habru Woreda, North Wolo health centers that enables to improve the use of patient information for making sound decision and effective problem solving. To achieve this goal of this study the investigator performs requirements identification by applying interview, observation and relevant document review techniques. Once the requirements are defined, object oriented system analysis and design methodology was employed. Analysis, design and implementation of the proposed system are performed using the UML tools for analysis and design, and C# programming language and Microsoft SQL for implementation stage of the prototype system. Finally, the project concluded automating the existing paper-based patient record system of the health centers plays a great role in improving the health service delivery of the country. As a prototype system the current study focuses only on automating the OPD of health centers and, hence further work will be expected that enhance the functionality of the system [25].

The EMR called care ware was adapted from US and deployed in Uganda in 2003 to support HIV treatment. Other developing country implementing the Electronic recording system was Malawi. In this country a touch screen patient management information system used since 2001. Then the extensive use of this system directly by health care workers in a poor country with limited IT skills is a convincing demonstration of the potential of EMRs with user friendly data entry mechanism [26].

In Ethiopia, DHIS1.4 (statistical software) adapted from South Africa has been implemented in some of its regions and shows a significant progress in delivering timely and quality data to the higher levels. After seeing such changes FMOH start to implement computerized system in all levels of the health system. But it was difficult to address throughout the country due to economic and infrastructural problems. And a gateway system is implemented which allows reporting the data from the lower level facilities using paper and entre electronically in the provincial or zonal levels to report to the regional and central (national) levels [27].

A project report on hospital management system was done by Mansi chitakara et.al. In India the result of the project report can be used in any hospital, clinic, and dispensary, or pathology, lab. The Software includes: Maintaining Patient details, Providing Prescription, Precautions and Diet advice, Providing and maintaining all kinds of tests for a patient and Billing and Report generation. This project used desktop application to be developed in VB 6.0 having Ms Access as backend, Database Design (Ms Access), Form Design (VB 6.0), Coding (VB 6.0), Testing (VB 6.0) and Reporting Tool (Data Report) [28].
“In Ethiopia, the implementation of Electronic Medical Record is through software called Smart Care. Tulane University’s Technical Assistance Program for Ethiopia (TUTAPE) is developing the Smart Care software in partnership with Tulane University, CDC and the Federal Ministry of Health Ethiopia (FMOH). Smart Care was first developed, tested and deployed in Zambia by CDC for HIV/AIDS care and treatment. Besides the rich and advanced functionality and features, Smart Care has also been proven to work in limited resources environment of developing countries particularly in Africa [29].
CHAPTER THREE

Methodology
The proposed project was used structured system analysis and design approach with the iterative waterfall model and includes requirement gathering, analysis and design of the proposed system.

3.1 Study Setting
This organizational project was conducted in West Arsi zone, Shashemane woreda, Kuyera town about 238 km south of the capital city Addis Ababa. It is one of the most experienced hospitals of the region with more than 50 yrs of service for the population of the area which is currently estimated to be 2.1 million people. The study was made in Shashemane Referral Hospital from January to May 2014.

3.2 Source and Study Population
The source populations were all health workers in SRH. The study population was all physicians at OPD and IPD, Nurses, Data clerk, HMIS officer and system administer who participate in patient registration, patient data recording, treatment, report generation and dissemination.

3.3 Data Collection Techniques
The required data for the development of the proposed system were collected by the use of the following data collection tools: -

3.3.1 Interviewing
Interviews were conducted with the medical Doctors working at OPD’s, HMIS officer and Data clerk and ward nurse to find out what difficulties they encountered with the existing system. The tools that were used to gather interview information’s were closed and open ended questionnaire.

This technique was chosen because:
- It permits clarification of questions
- Has high response rate than written questionnaires
- It is suitable for use with both literate and illiterates
- Get full range and depth of information
- Develops relationship with client
- Can be flexible with client

3.3.2 Observation
This technique was used to gather accurate information about how the system actually operates, particularly about processes. The workers at hospital systematically watched and recorded the behaviors and characteristics of operations and processes in the hospital. Prior to the observed job at the hospital observation check list were prepared as a tool to observe
the day to day to day activities in the OPD’s, HMIS office, Medical Record Unit and Ward’s

Observation techniques have many advantages:
- It gives more detailed and context related information
- It permits the collection of information on facts not mentioned in the interview
- It permits tests of the reliability of the responses to the questions
- View operations of a program as they are actually occurring
- Can adapt to events as they occur

3.3.3 Document Analysis
Document and formats were reviewed including patient charts, registers, tally sheets, periodic reports that are available at OPD’s, Medical Record Unit and HMIS office were reviewed to look upon the usual data recording, completion, processing and reporting process. This technique was used because:
- It is inexpensive because the data is already there
- It permits examination of trends over the past
- Doesn’t interrupt program or client’s routine in program

3.4 Requirement Analysis
The result of the Interview, Observation and Document review were analyzed immediately after requirement gathering. Finally, the result was presented by DFD and activity diagram.

3.5 Systems Design and development methodology
The proposed project used the Structured System Analysis methodology because of the following reasons:
- It structures a project into small, well defined activities and specifies the sequence and interaction of these activities.
- It uses diagrammatic and other modeling techniques to give a more precise (structured) definition that is understandable by both users and developer.

3.5.1 Analysis and Design Technique tools
- The technique that were used for analysing and designing system were:
  - Data Flow Diagram
  - Use case diagram
  - ER diagram
  - System Architecture
  - Relational Database Design
- Tools that used were Visio 2007 for Use case diagram, Data Flow Diagram, System Architecture and ER diagram and Access 2007 for Relational Database Design were used.
3.5.2 Development environment tools

Software that was proposed for implementation phase:-

- WAMPSERVER
  - PHP
  - My SQL
    - Apache
- For the database the selected software was: SQL server 2008
- For this project the suggested programming language was:-
  - PHP
  - HTML

**Front end:** HTML enable the construction of easy and intuitive user interface for accessing the database and any browser can display and html document [18].

**Middle end:** PHP enables links of the text entered in the created graphic user interface to be sent to the database [18].

**Back end:** SQL server it’s easy to use, inexpensive database language it can run on a variety of operating system such as window, Linux, Unix’s/2 and others , its secured with technical support widely available on the internet but most of all it support large database[18].

3.6 Dissemination of results

The result of the project disseminated by using formal report to Shashemene Referral Hospital and Addis Ababa University school of Information science and school of public health for partial fulfillment of Msc. degree in health informatics.

3.7 Ethical consideration

Ethical clearance was sought from Addis Ababa University research and ethical committee of Addis Ababa University Medical faculty through School of Public Health and permission from SRH medical director were obtained before the proposed project was commenced. Before requirement gathering the respondents were asked for their permission to be part of this project and they were told that as they have right not respond or participate in the project.

3.8 Operational definition

**Doctor:**-a health professional who treat patient and responsible person for patient life.

**Nurse:**-a health professional who work in health institution to give care for patients.

**Data clerk:**-a person in charge in hospital to register new patients and update repeat patients.

**HMIS officer:**-An IT professional or health professional assigned in the hospital for generation of reports and dissemination.
Patient/client: people who get service from health facilities.
Ward: is a place found in the hospital where patients get bed and treated.
Health facilities: health institutions like health centers, clinics, hospitals etc.

CHAPTER FOUR

DISCUSSION OF RESULTS

The rationale of this chapter is to illustrate the requirements needed to design a patient record system for SRH.

4.1. Current System Description

Currently, the patient record system is working manually. According to the respondents this working condition has different drawbacks. Some of the drawbacks mentioned were:

- Searching previous patient history is boring and time taking
- There may be lose of patients file
- It is costly

4.1.1. Identification of Inputs and Outputs of the System

In an open system, there are usually inputs flowing into the system and outputs are produced after the inputs have been processed.

Inputs: are attributes that can be stored on a database. They are the major raw materials to arrive at the output.

Inputs of the current manual system of the hospitals were:

1. Each patient must give full personal information for the patient record office
2. Each patient must pay the required payment in the record office or bring free treatment paper from woreda administrative office
3. If repeat patient he/she must bring service card
4. In referral cases the patient must bring referral papers
5. The patient must tell about his/her illness to the Physician

Outputs: are processed inputs

Outputs of the current manual system of the hospitals were:

1. The record office give service card for new patients
2. The doctor give a prescription paper for the patient

4.2 Analysis and Requirement Specification

A requirement is simply a statement of what the system must do or what characteristics it needs to have. During a systems development project, requirements will be created that describe what the business needs (business requirements); what the users need to do (user requirements); what the software should do (functional requirements); characteristics the
system should have (nonfunctional requirements); and how the system should be built (system requirements) [30].

4.3 Hardware Requirement and Software Requirement

This section describes the hardware components and software requirements needed for effective and efficient running of the system.

Table 2: Hardware Requirements

<table>
<thead>
<tr>
<th>Hardware</th>
<th>Minimum System requirement</th>

</table>

4.4 System Requirement specification

Software Requirements Specification is the requirements work product that formally specifies a design of patient record system.

4.4.1 Functional requirements

Functional requirements are associated with specific functions, tasks or behaviors the system must support. These specify particular results of a system. The following requirements are some of the functional requirements that, the proposed system will exhibit.

- Register new /update repeat patient detailed information
- Search patient detail
- Assign patients to different case team
- Mange Out patient
- Manage admitted patient
- Manage bed schedule
- Manage nursing care plan
- Manage discharge summary
- Manage user account
Generate report, such as, patient detailed report, patient admission report, and patient discharging report.

In addition, this setup leads to the functional requirements described below.

**System Login:-**

User shall type

- Username :-shall be unique given to specific user
- Password: - length of the maximum character char (30) and minimum character char (6).

Username and password match successful login in to the system direct the users to the home page of the Patient Record System.

**Registration Management**

Users shall have access to register/Update/Save patient information .

**Case Complete**

The users shall close out the monitoring of registering of patients and facilities that have been given to the patient. Once a case is closed the user shall be ready for the next request with the homepage displayed on the form.

**Logging Out**

The Users shall log out of the system by clicking "Log Out".

**4.4.2 Non- functional requirements**

Non-functional requirements are requirement that specifies criteria that can be used to judge the operation of a system, rather than specific behaviors. This should be contrasted with functional requirements that define specific behavior or functions. They are often called qualities of a system.

**Performance:-** The system is capable of handling huge amount of data within the database in different table. This system can handle the information of the patients sufficiently as much as possible in the hospital reception department.

**Reliability: -** Users can have both hard copies in printed report format and softcopy of that data that related to the information of the patient using separated storage media in order to minimize loss of different confidential information of patient if it is facing faller of proposed system.

**Maintainability: -** During the fault occurrence there is less chance to lose data within the system because there is continues data backup from the server. In addition to this it is easy
to maintain the system due to hierarchal separation among database, business model and user interface hence, the system can be maintained easily.

**Availability:** - The system is available 24 hours, because, the referral hospital works 24 hours a day and 7 days a week. In order to achieve the system to work full time it needs Uninterruptable Power Supply.

**Security:** - Security becomes crucial issue in the proposed system. A user must login to the system with user name and password. The system has two groups of users: the Administrator and Limited user. The Administrator user has full privilege to perform on the system. And the Limited user can only perform limited operations.

### 4.5 Business Rule

A business rules approach is a different way of thinking about the analysis process. Rather than focusing on system requirements, the analysis process is refocused on business rules. Instead of asking users what they want their system to do, they are asked about how their business or organization works.

- **BR1.** Determine validity to access the system
  - BR 1.1. The user should have valid user name
  - BR 1.2. The user should have valid password

- **BR2.** Validate Patient information.
  - BR2.1. Validate in-patient information
  - BR2.2 Validate personal information of In-patient
  - BR2.3. Validate contact person information of In-patient

- **BR3.** To receive nursing care plan the patient should stay more than 24 hr in hospital

- **BR4.** The patient shouldn’t pay if he returns less than 30 days of his previous registration

- **BR5.** If the patient can’t afford he/she should bring seaport paper woreda Administrative office.

### 4.6 List of User Interface

The following user interfaces were identified:

- **UI1.** System Login Form
- **UI2.** Invalid Login Form
- **UI3.** HOME PAGE
- **UI5.** Patient Registration Form
- **UI6.** Department Information registration Form
- **UI7.** Employee Information registration Form
- **UI8.** Admission Form
- **UI9.** Discharging Form
- **UI10.** Appointment scheduling Form
- **UI11.** Diagnosis Information Registration Form
20

4.7 System Use Case Model

The functionalities of the proposed system, as mentioned in the previous sections, are explained in terms of system use cases in the following section. The dynamic models of the use cases, the interaction with respect to time are described using activity diagrams.

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Clerk</td>
<td>The Data clerk will register new and repeat patient</td>
</tr>
<tr>
<td></td>
<td>Search patient by his/her name or date</td>
</tr>
<tr>
<td>Ward Nurse</td>
<td>The ward Nurse will carry out admission, Nursing process and discharge processes.</td>
</tr>
<tr>
<td>HMIS Officer</td>
<td>The HMIS Officer will view, generate and print the report from the system</td>
</tr>
<tr>
<td>Physician</td>
<td>Physician will give Medical service to the patient.</td>
</tr>
<tr>
<td></td>
<td>View the patient detail and add a new patient history.</td>
</tr>
<tr>
<td>System Administrator</td>
<td>Maintain the system of User Account and take back up.</td>
</tr>
</tbody>
</table>

4.8 List of Use case Identification

Login user account
Patient registration
Search patient information
Assign patient for different case team
Mange patient at OPD
Manage bed schedule
Manage admitted patient
Mange nursing care plan
Maintain discharge summary
Generate report
Manage user account
4.9 Use Case Modeling

For better understanding of the requirements of the system, use case modeling is being used. A use case diagram illustrates in a very simple way the main functions of the system and the different kinds of users who will interact with it and also the use case communicates at a high level what the system needs to do. Each use case describes how an external user triggers an event to which the system must respond [30]. The use case diagrams illustrated below are the only samples of the whole system.

![Use case diagram for management of patient at OPD](image)

**Fig 1:** Use case diagram for management of patient at OPD
Fig 2: Use Case Diagram for Management of Patient at IPD
Fig3: Use Case Diagram for Generation of Report by HMIS Officer
### Table 5: Use Case 1: Login

<table>
<thead>
<tr>
<th>Use Case ID:</th>
<th>UC-1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Case Name:</td>
<td>Login</td>
</tr>
<tr>
<td>Actors</td>
<td>Users</td>
</tr>
<tr>
<td>Description:</td>
<td>This use case is used to accept the user ID and password and authenticate User to access data input and data viewing screens.</td>
</tr>
</tbody>
</table>
| Normal Flow: | 1. The use case starts when a user opens a form which prompts user to enter user ID and password  
2. The user enters user ID and Password on the “System Login form UI1” and click [login],  
3. The system verifies if the user ID and password is valid,  
4. System informs successful login message, The system deactivates/hides buttons that are not to be manipulated by that specific user type,  
6. Use case ends when system displays a general user interface with buttons to jump to different windows or forms. |
| Post condition | user enter in to the system to perform his/her work |
| Alternative Flows: | 3a. Invalid user ID and password  
1. The system kindly request the user to enter valid ID and password (allow this 3 times) (BR 1)  
2. After the 3rd trial system informs user to contact system administrator for valid user ID and password. |
| Post condition: | The system prevents user to enter |
| Frequency of Use: | 50-80 |
## Table 6: Use Case 2: Patient Registration

<table>
<thead>
<tr>
<th>Use Case ID:</th>
<th>UC-2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Case Name:</td>
<td>Patient Registration</td>

<tr>
<td>Description:</td>
<td>• This use case helps the data clerk to register the new patient/update repeat patient on the system.</td>
</tr>
</tbody>
</table>
| Trigger:      | • Patient wants to register  
                • Patient brings referral paper |
| Preconditions:| • User has been authenticated |
| Normal Flow:  | 1. Data Clerk clicks Out-Patient Registration Screen from “UI3 Home Page screen”,  
                2. System Display “UI5 patient registration form “ with [add, update, save, cancel, search] buttons,  
                3. The Data Clerk checks whether the patient is new or repeat,  
                4. The Data Clerk order the patient pay for service ,  
                5. The Data Clerk Receive receipt number from patient and [record] receipt number and click [save] button,  
                6. The Data Clerk takes patient information and click [save] button,  
                7. The system validates the correctness of the entered information via “BR2.2. Validate Out-Patient Information “,  
                8. The Patient registered as a new patient,  
                9. The Data Clerk click on [print] button ,The system print Service identification card |

**Post condition**

Transfer patient information to OPD case teams

**Alternative Flows:**

3.1 If repeat patient the data clerk clicks [update] button  
**Post condition:** The patient information is updated  
4.1 The patient my bring free treatment paper from wareda administration office  
**Post condition:** The patient will be registered without payment and updated if he/she comes below 30 days (BR 4).
6.1 The system determines the entered information is incorrect
6.2 The system displays the Data Clerk to re-enter patient information through “UI12 Invalid information screen”.

**Post condition**: The system start again at step 2

**Frequency of Use**: 100-250

---

**Table 7: Use Case 3: Search Patient Information**

<table>
<thead>

<tr>
<td><strong>Trigger</strong>:</td>
<td>Request from the patient/client</td>
</tr>
<tr>
<td><strong>Preconditions</strong>:</td>
<td>The patient history should be registered in the patient database before this time</td>
</tr>
</tbody>
</table>
| **Normal Flow**:   | 1. User enter in to the login form through “UI1 System Log in from”,
                   | 2. User then click [Search] button to search the patient in the database though user page,
                   | 3. The system view search form with list of search options like [Name][MRN]etc,[search],[cancel] buttons,
                   | 4. The User fills the search options to search via ” Patient search form UI 15” in the patient database and clicks [search] button,
                   | 5. The search patient information is displayed on user page. |
| **Post condition**| Search is successful or not |
5. System determined the patient is not found
5.1 System Inform user the searching result
is not found through “UI12 Invalid
information Screen”

Post condition: The system returns to “UI 5
Patient registration screen”

Frequency of Use: 50-80

Table 8: Use Case 4: Assign Patients to the Case Teams

<table>
<thead>

4.10 Activity Diagrams

4.10.1 Activity Diagrams of the proposed system

Activity diagrams are pictorial representation of activities and actions with branched support of choice. Activity diagrams describes: The coordination of activities to give a service and Activities needed to achieve some operations.
The following listed activity diagrams were the only sample of the whole system

Fig 4: Activity Diagram for Patient Registration
Fig 5: Activity Diagram for Patients Treated at OPD’s
Fig 6: Activity Diagram of Nursing Care Plan for Admitted Patients
**Fig 7:** Activity Diagram for Writing of Discharge Summary for Discharged Patients
4.11 Process Modeling
A process model is a graphical way of representing how a business system should operate. It illustrates the processes or activities that are performed and how data move among them. It involves defining the processes of a new system vis-à-vis an existing system. Process modeling allows you to project the process of the new information system from a less to a more detailed level. It explains how a system accesses and manipulates data from external entities using one or more processes or modules contained within the system. It uses DFDs [30].

4.11.1 Context Diagram
The context diagram defines how the business process or computer system interacts with its environment—primarily the external entities [30].

4.11.2 Data Flow Diagram
A data flow is a path for data to move from one part of the information system another. A data flow in Data Flow Diagram represents one or more data items [30].
Fig 8: Context Diagram of a Patient Record System
The following analyzed DFD’s were the only samples of the whole system.

**Fig9:** Data Flow Diagram of diagnose patient at OPD

Fig 12: Total Data Flow Diagram of IPD
4.12 System Design

Purpose

The purpose of system design is to give detail information for developing of the proposed system and it guides what to develop and how to develop it. In addition, the design phase decides how the new system will operate.

4.12.1 Data Modeling

Data modeling involves modeling the entire structure of the data to be used in a system. Data modeling basically involves modeling the important data items in the system as well as any relationships between the data items. ER modeling is a data modeling approach that shows the various data entities in a system and the relationships between these entities. Data modeling enables us to present only the structure of the data as required by the new system, without considering the database management system where the data is to be hosted [30].

4.12.2 Database Design

A database is a structured collection of records or data that is stored in a computer system. The structure is achieved by organizing the data according to a database model. The model in most common use today is the relational model [30]. For this particular project also relational database model was used.

4.12.3 Description of entities and their attributes

An entity: A person, partnership, organization, or business that has a legal and separately identifiable existence.

An attribute: is a property of a given entity.

Description of entities and there attribute will help for the developer of the system to identify the relationship between the entities and the associations needed between the entities.
<table>

4.12.4 Entity Relationship diagrams

The entity relationship diagram (ERD) is the most common technique for drawing a data model, a formal way of representing the data that are used and created by a business system. An entity relationship diagram (ERD is a pictorial representation of entities and the relationship between them [30]. The following ER diagrams are created by use of Visio 2007 and Ms Access 2007.

**Fig 13: ER Diagram of Patient Record System**

Fig 19: ER Diagram of Patient and Ward Nurse
Fig 20: ER diagram of Patient and Ward Nurse

Fig 21: ER Diagram of Patient and Treatment
4.13 System Architecture
An important step of the design phase is the creation of the architecture design, the plan for how the information system components will be distributed across multiple computers and what hardware, operating system software, and application software will be used on each computer (e.g., Windows or Linux operating system software) [30].

Fig 22: System Architecture of Patient Record System
Project work communication

Making needed information available in a timely manner is very important and helps for effective communication with stakeholders.

CHAPTER FIVE

CONCLUSION and RECOMMENDATION

5.1 CONCLUSION
The core aim of this Project was to design a patient record system for SRH for recording of patient health history. Patient health history recording is mandatory it helps the health professionals to easily accesses health history and prevents them from prescribing drugs that has adverse effects which threatens patient’s life. Additionally, the design will help the hospital workers to have their contribution on the requirement gathering as the result they will get good patient record system that will help them in their day to day activities. Furthermore, the patient record system was designed by structured system design life cycle which is a good methodology to produce good document. The tools used for collection of requirements were open and closed ended questions for interview and observation check list were used to observe the day to day activities. The result of the study was displayed by use of DFD, activity diagrams, ER diagrams.

5.2 RECOMMENDATION
During the study of this project it was found that the hospitals do not have patient record system. They were using manual systems to keep patient record which has its own problem. An attempt was made to develop a design of a patient record system which gives a permanent solution when it is implemented. The following mentioned recommendations should be carried out by the hospital administration and other stake holders to solve poor patient data handling system of Shashemane Referral Hospital:

- Addis Ababa University and Shashemene Referral Hospital should work on implementation phase of this document.
- Addis Ababa University should make proper arrangements for students to use this document as starting point for further study.
- Shashemene Referral Hospital should buy computers and server which helps for implementation of the proposed design of a patient record system.
- Shashemane Referral Hospital should train workers of the hospital who participate in management of health information.

5.2.1 Opportunity and Lesson Learned
This project has helped to understand better what goes in the patient records system. This was effectively done through reading of literature and other related works. The whole process of developing design of a patient record system was an opportunistic challenge.

Database tables
Data base tables are designed of rows and columns which help to hold data elements. Database tables help to organize and group data by common characteristics or principles. The following listed tables were created by using of SQL (Structured Query Language) server 2008.

Table 1: Patient profile table with its attributes

<table>

Fig 5: Activity Diagram for login by users
Annex IV

List of Data flow Diagram
Data Flow Diagram helps to design data process

**Fig1**: Data Flow Diagram of Assign patient process
Fig2: Data Flow Diagram of check patient file process
Fig3: Data Flow Diagram of Manage Bed Schedule
**Fig4:** Data Flow Diagram of Mange Nursing Care Plan
Annex V

Interview questions and Observation check list

Interview Questions

Purpose: The interview questions will help to assess the current system and to design future patient record system for Shashemane Referral Hospital

General Information:

Interviewee: ______________________________
Responsibility: ____________________________

Closed ended question

1. In what way a patient record system was recorded?
2. Who are individuals involved in patient care?
3. What is the method used to collect reports from departments?
4. Who are the stake holders use your reports?
5. Do you think there are problems in the process of patient registration, treatment and report generation?

Open ended questions

1. Please mention the feature you need in the new system?
   ______________________________________________________________________________
   ______________________________________________________________________________
   ______________________________________________________________________________

2. What are your concerns and worries in deployment of the new system
   ______________________________________________________________________________
   ______________________________________________________________________________
   ______________________________________________________________________________
3. Observation check list

Department____________________
Date__________________________

<table>
<thead>
<tr>
<th>Process to be Observed</th>
<th>Yes</th>
<th>No</th>
<th>Remark</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Patient registration carried out according to standard</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2. Patient health records are placed in its places</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>3. Retrieval of patient record is it time tacking?</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. Is there any lost/damaged patient health records?</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>5. Do they use all formats in OPD/Ward</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>6. Do all physicians assess, Diagnose and treat patients according to standards?</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>7. Does reporting generation process is time taking?</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
