

2

A PALYNOLOGICAL-TAXONOMIC STUDY OF THE GENUS
ASYSTASIA AND A PALYNOLOGICAL STUDY OF
SOME RELATED GENERA IN THE ACANTHACEAE

A Thesis
Submitted to
School of Graduate Studies
Addis Ababa University

In Partial Fulfillment
of the Requirements for the Degree
of Master of Science in Biology

By
Ensermu Kelbessa

June 1982.

ACKNOWLEDGMENTS

I would like to extend my sincere thanks to Professor Olov Hedberg for guiding my interest towards palynological studies, for suggesting the topic, for guidance and supervision and for spending his valuable time to check the manuscript. My sincere thanks also go to Sue Edwards, my advisor, for her valuable advice and for spending a great deal of her time in checking and editing the manuscript.

My deep thanks are also due to the following: Dr. Siwert Nilsson, Dr. Bhoj Raj, Dr. Joseph Praglowski, Dr. Mats Thulin, Ato Mesfin Tadesse, Ato Asfaw Hunde, Mr. Mattias Iwarsson, Mr. Roger Svenson, Mrs. Elizabeth Grafstrom, Mrs. Marianne, Dr. Chr. Puff, Dr. Inga Hedberg and all staff members of the Palynological Laboratory of Stockholm and the Institute of Systematic Botany of Uppsala for their assistance.

I am grateful to the directors and all staff members of the following herbaria for sending me their valuable specimens to Uppsala: Jardin Botanique de l'Etat Bruxelles; Herbarium Universitatis Florentinae Instituto Botanico, Firenze; Swedish Natural History Museum, Botanical Section, Stockholm; the Botanical Museum of Copenhagen; the Botanical Museum of Uppsala; the Royal Botanical Gardens, Kew and National Herbarium, Addis Ababa.

Financial assistance for the thesis has been obtained from the Swedish Agency for Research Cooperation with Developing Countries (SAREC) through the Ethiopian Flora Project for which both are deeply acknowledged.

ABSTRACT

The pollen morphology of nineteen species of Acanthaceae: nine of Asystasia and ten of five other genera have been investigated using light and/or electron microscopes. The five genera Graptophyllum, Jacobinia, Justicia, Mackaya and Stygasia can be separated from each other by the number and character of apertures, exine stratification and/or by the nature of the "tremea area". The study has revealed that the pollen grains of the genus Asystasia are three-porate and the surfaces are provided with nine colpoid streaks. The sexine is smooth. The species can be separated from each other by the difference in the prominence of the colpoid streaks and by the nature of the sexinuous region around the pore.

A detailed study of the pan-tropical species A. gangetica (L.) T. Anders. has resulted in its subdivision into two geographical subspecies on the basis of corolla and style and stigma lengths. It is also supported by pollen size and seed morphology. The subspecies with long corolla and style and stigma is designated as subsp. gangetica and the one with short corolla and style and stigma subsp. micrantha. The distribution of both taxa is illustrated.

INTRODUCTION

Early studies of acanthaceous pollen were made by Bischoff, Frittsch and Von Mohl, but the taxonomic value of pollen characters in the classification of the family was first pointed out by Radlkofer (Long, 1970). Lindau (1895, 1897) classified the family Acanthaceae mainly on the basis of pollen morphological characters.

Recently many investigators have made contributions to pollen morphological studies in the family. Bhaduri (1944) studied thirty species of Acanthaceae and reported that dimorphism in size and shape have been found a definite character of the pollen grains of many of the species.

Campo (1955) made a detailed study of the pollen grains of Eranthemum nervosum R. Br. Raj (1961, 1965, 1973) investigated the pollen grains of 260, 2 and 143 species of Acanthaceae, respectively.

Sharma and Vishnu-Mittre (1963) examined the pollen morphology of eleven species of Acanthaceae; eight of Eranthemum and three of Pseuderanthemum. They distinguished four pollen types based on aperture and exine pattern and concluded that both genera are eurypalynous.

Vishnu-Mittre and Gupta (1966) investigated the pollen morphology of several species of Strobilanthes. They divided all the species into two groups based on the apertures: porate

and colporate types. They further distinguished two major types of pollen grains based on exine pattern: the banded and the spinulose types.

Petriella (1968) studied the pollen morphology of the genera of Argentine Acanthaceae. He investigated the pollen grains of thirty species in fifteen genera and concluded that it is possible to separate the genera on the basis of pollen characteristics except the genera Justicia and Jacobinia which can be separated from the rest but not from one another.

Hsieh and Huang (1974) dealt with the general morphology, vegetative and floral anatomy, palynology and geographical distribution of thirty four species of Taiwan Acanthaceae belonging to twenty genera. They established ten pollen types based on the aperture and exine stratification.

Medus and Sonokho (1974) studied the pollen morphology of eight species of Hygrophila. Brummitt et al. (1980) discovered pollen grains referable to Crossandra stenostachya which are so exceptional in size and shape that they are among the most remarkable ever reported in the plant kingdom (520x19 μ m).

Apart from the studies on pollen grains of one species of Asystasia Blume by Bhaduri, ten by Raj and three by Chaubal in the works quoted above, the pollen grains of many species of that genus have not been investigated.

The genus Asystasia was established by Blume (1826) on material from Java and the type species is A. nemorum Nees (A=intrusa Blume). According to Long (1970) forty species of Asystasia Blume have been described, chiefly from tropical Africa, Asia and the East Indies. In addition to these, Brummitt and Chisumpa (1978) described two new species of the genus from Malawi and Zambia.

The generic name is derived probably from the Greek word asystatos meaning not holding together, in reference to the wide-spreading valves of the dehiscent capsules (Long, 1970).

Linnaeus (1759) established Justicia gangetica on materials from India. The specific epithet alludes to the type locality, the Ganges River.

Nees (1832) described Asystasia coromandeliana on material from Coromandel, India. He included three varieties based on the degree of hairiness of the stem and leaves. Furthermore, Nees (1847) described seven varieties of A. coromandeliana. Nees based mainly on the hairiness of the stems and leaves except his variety alpha* micrantha which differ from the rest by its bigger leaves and from the variety alpha by its corolla and capsule which are half the size of those of variety alpha.

Many other taxa of the genus Asystasia Blume have also been described by Nees, but most of them are now designated as synonyms of A. coromandeliana Nees (Anderson, 1864; Baker, 1877; Clarke in Hooker 1884-1885, Clarke in Thiselton-Dyer, 1899-1900, 1901-1912; Cufodontis 1959-1966. Hiern, 1900; Hutchinson and Dalziel, 1963; Schwartz, 1939). However, the description of A. quaterna Nees does not agree with that of A. coromandeliana Nees, particularly regarding the length of calyx. In A. quaterna, Nees states that "the corolla tube is as long as the calyx", whereas in all specimens of A. coromandeliana investigated the length of the calyx is never equal to that of the corolla tube.

Klotzsch (1862) described eight species of Asystasia Blume on materials from Mozambique and its neighbouring islands. All of them have been found to be synonyms of A. coromandeliana Nees (Clarke in Thiselton-Dyer, 1899-1900). Anderson (1864) transferred Justicia gangetica L. (= Asystasia coromandeliana Nees) to A. gangetica (L.) T. Anders.

The chromosome numbers of A. gangetica (L.) T. Anders. have been counted by several workers (Naryanan, 1951; Grant, 1955; Kaur, 1965; De, 1966; Mangenot and Mangenot, 1970; Fernandes and Franca, 1975) and their findings indicate the occurrence of polyploidy in the species.

2. MATERIAL AND METHODS

This study is based on herbarium material obtained on loan from the following herbaria: BR, C, ETH, FI, K, S, and UPS (abbreviations according to Holmgren and Keuken, 1974). The pollen grains of nineteen species of Acanthaceae: nine of Asystasia Blume and ten species of five other genera have been investigated. Furthermore, the pan-tropical species A. gangetica (L.) T. Anders. s.l. has been revised on the basis of pollen and gross morphological characters.

2.1. PREPARATION OF POLLEN GRAINS FOR LIGHT MICROSCOPY

2.1.1. Acetolysis:

Flowers and/or buds were collected from herbarium material. These were placed in a dilute solution of wetting agent for a few minutes. Anthers were picked out under a dissecting microscope and placed in centrifuge tubes. The anthers were crushed with a glass rod and about five millilitres of glacial acetic acid was added and the mixture was centrifuged. After decanting, an acetolysis mixture (nine parts of glacial acetic anhydride and one part of concentrated sulphuric acid) was added drop by drop stirring the mixture with a glass rod. The mixture was then heated to about 95°C in a copper plate stirring frequently, until.

the colour of the mixture changed to yellow. After centrifuging, the solution was decanted and five millilitres of distilled water was added to the sediment which was washed thoroughly using a mixer. The mixture was filtered twice through a mesh of brass net and then centrifuged.

- 2.1.2. Bleaching: When pollen grains of Asystasia Blume were heated to more than 95°C , the mixture changed to brown and the pollen darkened. This required dividing the sediment: half of the sediment was taken for chlorination to bleach the pollen grains for exine studies and the other half was placed in a few drops of 50% glycerine for size studies.

To bleach the darkened pollen grains, five millilitres of glacial acetic acid, one to two drops of sodium chlorate solution and two or three drops of concentrated hydrochloric acid were added and the mixture stirred. The mixture was then centrifuged and decanted. The sediment was washed twice using distilled water, centrifuged and decanted. The chlorinated and unchlorinated pollen grains were mixed. About twelve drops of 50% glycerine were added and the mixture allowed to

stand for fifteen minutes. The mixture was centrifuged and decanted. The centrifuge tube containing the sediment was allowed to stand upside down on a filter paper for two hours to remove the glycerine before slides were made.

2.1.3. Slide Preparation

Glycerine jelly was cut into a number of pin-head sized cubes. A pin-head sized cube was taken on a clean needle, the pollen material was touched with the jelly cube and transferred to a clean labelled slide. The slide was warmed so that the jelly melted and the melted jelly was stirred with the same needle used to pick up the sample to avoid contamination. The jelly was then rewarmed and a circular cover glass was placed on the pollen material and sealed off with paraffin, melting point about 70°C.

2.1.4. Microscopic Investigation

Microscopic investigations were carried out using Optic Leitz Wetzlar for most specimens of Asystasia gangetica (L.) T. Anders. and Olympus BH for others. All measurements were made using oil immersion and ocular micrometer. The measurements were taken as the average of ten (rarely less)

acetolyzed and unchlorinated pollen grains. As noted by Erdtman (1969) the chlorinated pollen grains should not be used for size measurements because they swell in bleaching. These were used to study the exine stratification.

2.1.5. Photography

All photographs were taken with oil immersion using Carl Zeiss and Olympus photomicrographic cameras. Slides made during the study are kept in the Palynological Laboratory of the National Herbarium, Addis Ababa University with duplicates in the Palynological Laboratory of the Swedish Natural History Museum, Stockholm.

2.2. PREPARATION OF POLLEN GRAINS FOR SCANNING ELECTRON MICROSCOPY

Pollen grains were acetolyzed as above. After acetolysis, the sediment was washed twice using distilled water, centrifuged and decanted. The pollen material was then kept in 30, 50, 80, 95 and 100 per cent acetone for fifteen minutes in each concentration. The pollen material was allowed to stand in 100 per cent acetone or it was directly transferred to a clean bronze cube (stub) using micropipettes under a dissecting microscope. The pollen material was then spread over the

surface of the stub and then kept in a dust free area or the stub with the pollen grains was coated with gold in Geol Fine Coat and the pollen grains were analyzed and scanned with Geol JSM-25S II Scanning Electron Microscope.

2.3. PREPARATION OF POLLEN GRAINS FOR TRANSMISSION ELECTRON MICROSCOPY

Anthers were removed under a dissecting microscope using forceps and placed in vials. TAG (solution of 1 per cent tanic acid and 2 per cent glutaraldehyde in 0.1M phosphate buffer Sørensen of pH 7.4) was added and the mixture was allowed to stand for two hours. The pollen material was then dehydrated using acetone of 30, 50, 70, 95 and 100 per cent, allowing for fifteen minutes in each concentration. After four changes of 100 per cent acetone, the pollen material was placed in 1:2 ratio Spurr: acetone and allowed to stand for two hours. The pollen material was then transferred to a concentrated Spurr and allowed to stand for twelve hours. After replacing the old Spurr with a freshly made Spurr, the pollen material and the Spurr was transferred to a small embedding capsule and placed in an oven (70°C) for five hours, checking the hardness of the capsule and Spurr at intervals.

After the capsule attained proper hardness, it was cut lengthwise and the Spurr with the pollen material was removed. The material was then fixed in a holder under a binocular microscope and trimmed into a pyramid to expose the pollen bearing part of the anther for cutting.

After cleaning the knife with pith tissue, it was mounted in a holder in a slightly curved position in a trough. The trough was filled to the brim with water and fixed to the microtome (Ultratome Model 4801 A main unit and model 4802 A Control Unit). The object holder was screwed in place and the pyramid was adjusted. The screws controlling the speed and thickness of the sections were adjusted and a final adjustment for sectioning was made under a binocular microscope.

The pyramid was brought to the level of the knife. The trough holding the knife was filled with distilled water to the brim using a syringe and the motor was started. After enough sections were made, the motor was stopped. The sections in ribbon were separated with a hair inserted in a tooth-pick and collected on grids of copper.

Uranyl acetate solution was transferred to a small plastic beaker using a pipette. The sections were placed in the beaker, covered with a dark cloth and allowed to stand for fifteen minutes. After rinsing the sections with

distilled water of pH 4, each grid was placed in a drop of lead citrate in a petri-dish and kept in the dark for fifteen minutes. The sections were rinsed using distilled water of pH 8 and placed near potassium hydroxide crystals in a petri-dish to remove water. The sections were removed from the grids and allowed to dry by placing on lens papers. Then the sections were replaced in the grids and kept in a dust free place. The sections were observed and photographed using transmission Electron Microscope (Model 10A/EM 10B).

2.4. MATERIAL FOR GROSS MORPHOLOGICAL STUDIES

The morphological studies of Asystasia gangetica (L.) T. Anders. s.l. are based on materials obtained on loan from the herbaria earlier mentioned. A total of 526 specimens were received. All of them were inspected but only 96 specimens which had enough flowers, leaves and/or fruits and seeds were measured and recorded in detail. Both the vegetative and reproductive parts were measured using a hand rule assisted by a binocular microscope when necessary. Each figure (number) represents an average of three or more measurements except for parts such as stamens and pistils which were based on a single measurement due to lack of enough flowers on a specimen.

3. RESULTS AND DISCUSSION

3.1 EXAMPLES OF POLLEN MORPHOLOGICAL VARIATION IN THE ACANTHACEAE

3.1.1 Descriptions of Pollen Grains

Graptophyllum pictum Griff., New Guinea III. 1958
Bergman 255 (S). Fig. 1. A-C. Pollen grains radially
symmetrical, isopolar, 3-colporate, peritreme, prolate-
spheroidal, $59 \times 56 \mu\text{m}$ (P/E. 100 = 105). Pollen grains
oval in equatorial view, amb circular.

Apocolpium diameter $17\mu\text{m}$. Colpi $44 \times 5\mu\text{m}$ with
tapering ends, membrane granular. Ora circular, $3\mu\text{m}$
in diameter. Each apertural region has two colpoid streaks,
 $33 \times 1\mu\text{m}$ and tapering towards the poles (shorter and
narrower than the colpi).

Exine $4\mu\text{m}$ thick at poles, $3\mu\text{m}$ thick at equator.
Sexine $2.5\mu\text{m}$ thick at poles, $2\mu\text{m}$ at equator, tectate.
Tectum provided with perforations that are circular to
irregular in shape. Nexine $1.5\mu\text{m}$ thick at poles, $1\mu\text{m}$
at equator.

Note Raj (1961) described the pollen grains of this
species as 3-porate & the sexine reticulate. But this
study has revealed that the pollen grains are 3-colporate
and the sexine is smooth.

Jacobinia glaziovii Hiern, Brazil V. 1902 Dusén

233 (S). Fig. 2. A-C. Pollen grains 2-colporate, isopolar, bilaterally symmetrical (59 x 34 x 25 μ m).

Colpi 52 x 4 μ m, tapering towards the poles, membrane granular. Ora lalongate, 4 x 6 μ m. Each apertural region has two colpoid streaks which are interrupted by four rows of circular, reticulate insulae (4.5 μ m in diameter).

Exine 3 μ m thick at poles, 4 μ m at equator. Sexine 2 μ m at poles, 3 μ m at equator, reticulate.

Reticulum homobrochate. Muri straight, less than 1 μ m wide. Lumina circular to polygonal, less than 1 μ m in diameter. Nexine 1 μ m thick at poles a little more than 1 μ m at equator.

Justicia flava (Vahl) Vahl, Ethiopia: Eritrea mooney 8005; Gilbert 1235 (both ETH). Pollen grains radially symmetrical, isopolar, 3-porate, pleurotreme, prolate 45 x 27 μ m (P/E $\cdot$ 100 = 166). Pollen grains oval in equatorial view, amb triangular.

Pores circular, 3 μ m in diameter, membrane granular. Each apertural region has a faint colpoid streak passing through the pore.

Exine $2\mu\text{m}$ thick at poles, $7\mu\text{m}$ at equator.

Sexine $0.5\mu\text{m}$ thick at poles, $4\mu\text{m}$ at equator, $\pm$ reticulate (ectosexine about $0.5\mu\text{m}$ thick, $\pm$ undulating). Nexine $1.5\mu\text{m}$ thick at poles, $3\mu\text{m}$ at equator.

J. hyssopifolia L. Asplund 585 (UPS). Pollen grains 2-colporate, isopolar, bilaterally symmetrical (54 x 40 x ? μm).

Colpi 25 x 4 μm , tapering at both ends, membrane granular. Ora lalongate, 6 x 8 μm , margin thickened. Each apertural region has two faint colpoid streaks.

Exine $2.5\mu\text{m}$ thick at poles, $4.5\mu\text{m}$ at equator. Sexine $1\mu\text{m}$ thick at poles, $2\mu\text{m}$ at equator, $\pm$ reticulate. Nexine $1.5\mu\text{m}$ thick at poles, $2\mu\text{m}$ at equator.

Note: Raj (1961) described the pollen grains of this species as 2-porate, but it appears that they are 2-colporate.

J. natalensis T. Anders. South Africa: Natal Wood 1512 (UPS). Pollen grains radially symmetrical, isopolar, 3-colporate, pleurotreme, prolate, 42 x 29 μm (P/E. 100 = 144). Pollen grains oval in equatorial view, amb triangular.

Apocolpium diameter $20\mu\text{m}$. Colpi slightly tapering towards the poles ($34 \times 5\mu\text{m}$), membrane granular. Mesocolpium $17\mu\text{m}$. Ora lalongate, $6 \times 8\mu\text{m}$, margin thickened. Each apertural region provided with two colpoid streaks.

Exine $2\mu\text{m}$ thick at poles, $3\mu\text{m}$ at equator. Sexine $1\mu\text{m}$ thick, reticulate.

Reticulum appears to be heterobrochate. Muri straight, less than $0.5\mu\text{m}$ wide. Lumina polygonal, about $0.5\mu\text{m}$ in diameter. Nexine $1\mu\text{m}$ thick at poles, $2\mu\text{m}$ at equator.

J. pinguior C.B.Cl., Ethiopia: Kaffa Brehme s.n. (ETH).
Fig. 3 A-C. Pollen grains 2-porate, isopolar, bilaterally symmetrical ($47 \times 29 \times 23\mu\text{m}$).

Pores slightly lalongate, $3 \times 4\mu\text{m}$, membrane granular. Each apertural region has a faint colpoid streak passing through the pore, $23 \times 0.5\mu\text{m}$. Each apertural region is provided with two rows of about ten circular, reticulate insulae.

Exine $3\mu\text{m}$ thick at poles, $4\mu\text{m}$ at equator. Sexine $2\mu\text{m}$ thick at poles, $3\mu\text{m}$ at equator, $\pm$ reticulate. Nexine $1\mu\text{m}$ thick at poles, $2\mu\text{m}$ at equator.

J. schimperi (Hochst). Dandy, Ethiopia: Tigray
Gilbert & Getachew 2801 (ETH). Fig. 4. A-B. Pollen grains
2-porate, isopolar, bilateral (54 x 35 x 20 μ m).

Pores lalongate, 3 x 4 μ m, membrane granular. Each
apertural region is provided with a faint colpoid streak
passing through the pore, 30 x 0.5 μ m. Each apertural
region has four rows of circular, reticulate insulae (about
3 μ m in diameter).

Exine 2 μ m thick at poles, 6 μ m at equator. Sexine
2 μ m thick at poles, 3 μ m at equator, reticulate.

Reticulum homobrochate. Muri straight, less than
1 μ m wide. Lumina polygonal, mainly pentagonal, 1 μ m
in diameter. Nexine 1 μ m thick at poles, 2 μ m at equator.

J. trinerva Vahl, Ethiopia: Wollega Mooney 6845 (ETH).
Fig. 4C. Pollen grains radially symmetrical, isopolar,
3-colporate, pleurotreme, prolate, 40 x 24 μ m (P/E. 100 = 167).
Grains oval in equatorial view, amb triangular.

Apocolpium diameter 13 μ m. Colpi 37 x 5 μ m with
tapering ends and fusing at the poles, membrane granular.
Ora lalongate 4 x 6 μ m, margin thickened, mesocolpium
11 μ m. Each apertural region has two colpoid streaks,
each seems to fuse with its counterparts in the other
apertural regions.

Exine $2.5\mu\text{m}$ thick at poles, $3.5\mu\text{m}$ at equator.

Sexine $1\mu\text{m}$ thick at poles, $1.5\mu\text{m}$ at equator, reticulate.

Reticulum heterobrochate, Muri straight, less than $0.5\mu\text{m}$ wide. Lumina polygonal, less than $1\mu\text{m}$ in diameter. Nexine about $1.5\mu\text{m}$ thick at poles, $2\mu\text{m}$ at equator.

Mackaya bella Harv., South Africa: Natal 1885 Adlem 240 (UPS). Fig. 5. A-C. Pollen grains radially symmetrical, isopolar, 3-colporate, peritreme, prolate-spheroidal, $62 \times 59\mu\text{m}$ (P/E. 100 = 105). Pollen grains oval in equatorial view, amb circular.

Synoolpate, colpi $47 \times 6\mu\text{m}$ with tapering ends, membrane granular. Ora circular $9\mu\text{m}$ in diameter. Each apertural region is provided with two colpoid streaks, that are as long as the colpi but narrower ($47 \times 1\mu\text{m}$).

Exine $4\mu\text{m}$ thick. Sexine $2\mu\text{m}$ thick, tectate. Tectum smooth, provided with circular to slit-like perforations. Nexine $2\mu\text{m}$ thick.

Note: Raj (1961) described the pollen grains of this species as having a reticulate sexine whereas this study revealed that the pollen grains have a smooth sexine with perforated tectum.

Styasasia sp. nov., Tanzania: Bushiri XI. 1950

Faulkner K 731 (S) Fig. 5 D, Pollen grains 5-porate
spheroidal 53 μ m in diameter.

Pores 5 μ m in diameter, membrane granular. Exine
4 μ m (spinules not included). Sexine 1.5 μ m thick provided
with spinules 2.5 μ m long. Nexine 2.5 μ m thick.

Note: The terminology used is according to (Erdtman,
1969; Erdtman et al., 1961; Raj, 1961).

9. Colpi don't meet at poles; tectal
perforations with irregular shapes.....Graptophyllum
pictum

3.1.3. Discussion of Pollen Morphological Features:

Of the ten species of Acanthaceae belonging to five genera investigated, Justicia trinerva and J. natalensis have the smallest pollen grains while Graptophyllum pictum, Mackaya bella and Jacobinia glaziovii have the largest.

Based on apertures, the pollen grains can be divided into two types: the porate and the colporate. the porate pollen grains are found in Justicia flava, J. pinguior, J. schimperi and Styasasia sp. nov. The porate pollen grains can be subdivided based on number of pores. J. pinguior and J. schimperi have 2-porate pollen grains. J. flava has 3-porate whereas Styasasia sp. nov. has 5-porate pollen grains.

Similarly the colporate pollen grains of Graptophyllum pictum, Jacobinia glaziovii, Justicia trinerva, J. hyssopifolia, J. natalensis and Mackaya bella can be further subdivided based on the number of the apertures: the two colporate and the three colporate types. Two colporate pollen grains are found in Jacobinia glaziovii and Justicia hyssopifolia while three colporate pollen grains are found in Graptophyllum pictum, Justicia natalensis, J. trinerva and Mackaya bella.

The stratification of the exine varies being smooth in Graptophyllum pictum and Mackaya bella, spinulose in Styasasia sp. nov. and +reticulate in Jacobinia glaziovii and all species of Justicia.

Considering symmetry the pollen grains of Graptophyllum pictum, Justicia flava, J. trinerva, J. natalensis and Mackaya bella are radially symmetrical whereas those of Jacobinia glaziovii, Justicia pinguior, J. schimperi and J. hyssopifolia are bilaterally symmetrical.

In all pollen grains that have colpoid streaks, the colpoid streaks are wider at the equatorial region and taper towards the poles.

The pollen grains of the five genera can be separated from each other by their size, the number and character of the apertures and the exine pattern. The pollen grains of Graptophyllum pictum and Mackaya bella are 3-colporate, the sexine is smooth and the tectum is provided with perforations. They can be separated from each other by their size, nature of the colpi at the poles and the perforations of their tectum. The colpi meet at the poles (syncolpate) in Mackaya bella while the colpi do not meet at the poles in Graptophyllum pictum. The tectal perforations are circular to slit-like in Mackaya bella while they have irregular shapes in Graptophyllum pictum.

The pollen grains of Jacobinia glaziovii and six species of Justicia can be separated although they are closely related (both genera have reticulate sexine). The major diagnostic pollen characters are the nature of the colpi and the insulae in the "trema area".

The pollen grains of Styasasia sp. nov. can easily be separated from the rest by the number of apertures (5-zono-porate) and the spinulose grains.

3.2: POLLEN MORPHOLOGICAL VARIATION IN THE GENUS

ASYSTASIA BLUME

3.2.1. Description of Pollen Grains

A. calycina Nees, Ghana: Accra Dalziel 152 (C).

Fig. 6 A-C. Pollen grains radially symmetrical, isopolar, 3-porate with 9 colpoid streaks, pleurotreme, prolate, $81 \times 49 \mu\text{m}$ (P/E. 100 = 165). Pollen grains oval in equatorial view, amb triangular.

Pores circular, $4 \mu\text{m}$ in diameter, membrane studded with blunt and pointed processes. Each apertural region is provided with 3 colpoid streaks. "Trema area" provided with six circular insulae (about $5 \mu\text{m}$ in diameter).

Exine $5 \mu\text{m}$ thick at poles, $12 \mu\text{m}$ at equator. Sexine $2 \mu\text{m}$ thick at poles, $7 \mu\text{m}$ at equator, tectate. Tectum smooth, provided with densely spaced circular to slit-like perforations. Nexine $3 \mu\text{m}$ thick at poles, $5 \mu\text{m}$ at equator.

A. charmian S. Moore, Kenya: Thika XII. 1952 Verdcourt 849 (S). Fig. 7 A-B. Pollen grains radially symmetrical, isopolar, 3-porate, pleurotreme, prolate, $109 \times 66 \mu\text{m}$ (P/E. 100 = 165).

Pores circular, $5\text{ }\mu\text{m}$ in diameter, membrane granular. Each apertural region is provided with about 24 circular insulae of $7\text{ }\mu\text{m}$ in diameter. The insulae are arranged in four rows and are provided with perforations. The surface of the pollen grain is provided with nine colpoid streaks near and at the poles and fusing at the poles but interrupted by the insulae near and at the pores.

Exine $7\text{ }\mu\text{m}$ thick at poles, $20.5\text{ }\mu\text{m}$ at equator. Sexine $3\text{ }\mu\text{m}$ thick at poles, $14.5\text{ }\mu\text{m}$ at equator +smooth. Tectum provided with perforations at and near the poles and +reticulate in equatorial region between the pores. Nexine $4\text{ }\mu\text{m}$ at poles, $6\text{ }\mu\text{m}$ thick at equator.

A. drakebrockmanii Turrill, Kenya: Mandera Gilbert and Thulin 1450 (UPS), Fig. 8 A-G. Pollen grains radially symmetrical, isopolar, 3-porate, pleurotreme, prolate, $82 \times 50\text{ }\mu\text{m}$ (P/E. $100 = 164$).

Pores circular, $6\text{ }\mu\text{m}$ in diameter, membrane granular. Each apertural region is provided with three narrow colpoid streaks, the middle passing through the pore is wider than the lateral ones. The lateral colpoid streaks have irregular margins and are interrupted by about ten poorly delimited circular insulae near and at the pore.

Exine $6\mu\text{m}$ thick at poles, $11\mu\text{m}$ at equator. Sexine $3\mu\text{m}$ thick at poles, $7\mu\text{m}$ at equator, tectate. Tectum smooth, provided with perforations. Nexine $3\mu\text{m}$ thick at poles, $4\mu\text{m}$ at equator.

A. guttata (Forssk.) Brummitt (= A. somalensis (Franch.) Lebrum & Touss.), Ethiopia: Sidamo, Zambaba x. 1980 Ensermu 440 (ETH). Pollen grains radially symmetrical, isopolar, 3-porate, pleurotreme, prolate, $87 \times 52\mu\text{m}$ (P/E. $100 = 167$).

Pores circular, $4\mu\text{m}$ in diameter, membrane granular. Each apertural region has three colpoid streaks of which the middle passing through the pore is prominent whereas the lateral ones are visible only near and at the poles. "Trema area" provided with about 18 circular insulae (SEM).

Exine $7\mu\text{m}$ thick at poles, $15\mu\text{m}$ at equator. Sexine $3\mu\text{m}$ thick at poles, $11\mu\text{m}$ at equator (ectosexine undulating), tectate. Tectum smooth, provided with perforations. Nexine $4\mu\text{m}$ thick.

A. macrocarpa Nees, India: Bengal III. 1932 Parker 3206 (S). Fig. 9 A-B. Pollen grains radially symmetrical, isopolar, 3-porate, pleurotreme, prolate, $65 \times 46\mu\text{m}$ (P/E. $100 = 141$). Pollen grains oval in equatorial view, amb triangular.

Pores circular $6\ \mu\text{m}$ in diameter, membrane granular. Each apertural region is provided with one prominent colpoid streak, the middle that passes through the pore, and two faint colpoid streaks with irregular margins.

Exine $3\ \mu\text{m}$ thick at poles, $5\ \mu\text{m}$ at equator. Sexine $1\ \mu\text{m}$ thick at poles, $2\ \mu\text{m}$ at equator, tectate. Tectum smooth and perforated. Nexine $2\ \mu\text{m}$ thick at poles, $3\ \mu\text{m}$ at equator.

A. oppositiflora Bremek., Celebes: Boetom II. 1929
Kjellberg 318 (S). Fig. 10 A-C. Pollen grains radially symmetrical, isopolar, 3-porate with nine colpoid streaks, pleurotreme, subprolate, $73 \times 49\ \mu\text{m}$ (P/E, 100 = 149).

Pores circular, $8\ \mu\text{m}$ in diameter, membrane studded with blunt and pointed processes. Each apertural region has three colpoid streaks. Each colpoid streak fuses with its counterparts in the other apertural regions. The nine colpoid streaks divide the exine into three broad and six narrow sexinuous regions.

Exine $5.5\ \mu\text{m}$ thick at poles, $7\ \mu\text{m}$ at equator.
Sexine $2.5\ \mu\text{m}$ at poles, $3\ \mu\text{m}$ thick at equator, tectate.
Tectum smooth and provided with densely spaced circular to

slit-like perforations. Each narrow sexinuous region is less than or equal to $4\ \mu\text{m}$ in width. Nexine $3\ \mu\text{m}$ thick at poles, $4\ \mu\text{m}$ at equator.

A. scandens Hook., Sierra Leone: Diano I. 1796 Peter 9 (UPS). Pollen grains radially symmetrical isopolar, 3-porate, pleurotreme, prolate, $86 \times 56\ \mu\text{m}$ (P/E. 100 = 157). Pollen grains oval in equatorial view, amb triangular.

Pores circular, $8\ \mu\text{m}$ in diameter, membrane granular. Each apertural region has three colpoid streaks which have irregular margins, especially at the pore where there are about six poorly delimited circular insulae (five circular and 1 more or less rectangular, diameter about $8\ \mu\text{m}$). The colpoid streak that passes through the pore is wider near and at the pore, tapering towards the poles while the lateral colpoid streaks are faint and have irregular margins.

Exine $5\ \mu\text{m}$ thick at poles, $7\ \mu\text{m}$ thick at equator. Sexine $2\ \mu\text{m}$ thick at poles, $3\ \mu\text{m}$ at equator, tectate. Tectum smooth, provided with circular perforations. Nexine $3\ \mu\text{m}$ thick at poles $4\ \mu\text{m}$ at equator.

A. schimperi T. Anders., Ethiopia: Hararge IX. 1980 Ensermu and Tamrat 335 (ETH); Gilbert and Thulin 64 (ETH); Somalia: Gelib Mooney 7657 (ETH). Pollen grains radially symmetrical isopolar, 3-porate, pleutrotreme, prolate, $73 \times 44\ \mu\text{m}$ (P/E. 100 = 165).

Pores circular, $3.5 \mu\text{m}$ in diameter, membrane granular. Each apertural region is provided with three colpoid streaks of which the middle, passing through the pore, is prominent while the lateral ones are visible only near and at the poles. Each apertural region has about ten circular insulae of about $7 \mu\text{m}$ in diameter. The insulae have perforations.

Exine $6 \mu\text{m}$ thick at poles, $15 \mu\text{m}$ at equator. Sexine $3 \mu\text{m}$ thick at poles, $10.5 \mu\text{m}$ at equator, (ectosexine undulating), tectate. Tectum smooth, provided with perforations. Nexine $3 \mu\text{m}$ thick at poles, $4.5 \mu\text{m}$ at equator.

Note: Raj (1961, 1973) has investigated the pollen grains of ten species and Chaubal (in Raj, 1973) three. The former has described the pollen grains as 3-porate whereas the latter as 3-zonicolporate. This study has revealed that the pollen grains of the genus Asystasia are 3-porate. The former author also described the exine pattern, the sexine as reticulate while this study has revealed that the sexine is smooth and tectum provided with perforations. There is some kind of reticulation in the "trema area" equatorially between the pores in A. charmian. The sexine of this species is intermediate between smooth and reticulate.

3.2.2. Key to the Species of Asystasia based on Pollen Characters.

1. Polar axis upto $67\mu\text{m}$; exine $4\mu\text{m}$ thick
at poles; A. macrocarpa
1. Polar axis more than $67\mu\text{m}$; exine
more than $4\mu\text{m}$ thick at poles.....2
2. "Trema area" provided with about
24 perforated insulae; polar
axis more than $88\mu\text{m}$; equatorial
diameter more than $56\mu\text{m}$1... A. charmian
2. "Trema area" provided with at
most 18 smooth insulae or insulae
absent; polar axis not exceeding
 $88\mu\text{m}$; equatorial diameter not
exceeding $56\mu\text{m}$3
3. The Trema area" provided with insulae.....4
3. The "Terma area" not provided with
insulae.....8
4. "Trema area" provided with 6 insulae....5
4. "Trema area" provided with more than
7 insulae.....6
5. Insulae all circular; exine $11-13\mu\text{m}$,
sexine $7-8\mu\text{m}$ thick at equator;
pores $3-5\mu\text{m}$ in diameter..... A. calycina
5. Insulae 5 circular and 1 rectangular;
exine $5-7\mu\text{m}$, sexine $2-3\mu\text{m}$ thick at
equator; pores $6-8\mu\text{m}$ in diameter..... A. scandens

6. Lateral colpoid streaks continuous
through the pores; oxine 9-11 μ m,
sexine 6-7 μ m thick at equator.....A. drakebrock
manii
6. Lateral colpoid streaks dis-
continuous at and near the pores;
oxine 13-16 μ m, sexine 9-12 μ m thick
at equator.....7
7. "Trema area" provided with about
10 insulae; polar axis 68-75 μ m;
equatorial diameter 42-48 μ m.....A. schimperi
7. "Trema area" provided with about
18 insulae; polar axis 81-92 μ m;
equatorial diameter 49-56 μ m.....A. guttata
8. The narrow sexinuous regions
on the lateral sides of the
pores more than 4 μ m wide,
tectal perforations in two rows or
irregularly arranged.....A. gangetica
8. The narrow sexinuous regions
on the lateral sides of the pores
less than or equal to 4 μ m wide,
tectal perforations in one row.....A. oppositiflora

4.3. Discussion of Pollen Morphological Features.

The pollen grain of all species investigated are radially symmetrical. The shape of the pollen grains does not show much variation. It is prolate in all species. The smallest pollen grains are found in A. macrocarpa (65 x 46 μ m) and the largest are found in A. charmian (109 x 66 μ m).

Considering aperture, the pollen grains of all species are 3-zonoporate and are provided with nine colpoid streaks, three in each apertural region. These colpoid streaks are equally prominent in four species, viz. A. calycina, A. drakebrock manii, A. gangetica and A. oppositiflora and relatively faint in two: A. macrocarpa and A. scandens. The colpoid streaks are interrupted by insulae at and near the pores in A. charmian, A. guttata and A. schimperii.

The major pollen morphological character that helps separate the nine species is the region around the pore. The pollen grains of A. gangetica and A. oppositiflora are very similar. However, they can be separated by the differences in width of the narrow sexinuous regions around the pore. The narrow sexinuous regions on the lateral sides of the pore are broader in A. gangetica (more than 4 μ m) than in A. oppositiflora (less than or

equal to $4\ \mu\text{m}$). Furthermore, the perforations of the tectum are in two rows or irregularly distributed in the former whereas they are found in one row in the latter.

The pollen grains of A. macrocarpa and A. scandens are similar in that the colpoid streaks have irregular margins. They can be separated by the presence or absence of insulae. The pollen grains of A. macrocarpa have no insulae in the "Trema" area" whereas those of A. scandens have six insulae (five circular and one rectangular).

The pollen grains of A. charmian, A. gutta and A. schimperi are similar in the aperture region. They can be separate from the other species by having faint colpoid streaks (especially lateral ones) which are visible only near and at the poles. They are separated from each other by the presence of about 24 circular and perforated insulae in A. charmian; ten circular and perforated insulae in A. schimperi and 18 circular and poorly delimited insulae in A. guttata (SEM). The pollen grains of A. charmian also differ from the other two by the more or less reticulate sexine in the equatorial region between the pores. These three species can also be separated from each other by the difference in the pollen grain size (LM).

The stratification of the exine in all species has the same pattern although there is some deviation in A. charmain. The pollen grains of all species have a generally smooth sexine but in A. charmian there is some form of reticulation of the sexine. The tectum in the pollen grains of all species is perforated. The perforations are circular to slit-like in most species and are similar in shape and size. But in the pollen grains of A. macrocarpa and A. scandens the perforations are smaller than in the others and they are circular.

The pollen grains of the nine species of Asystasia can be separated from each other based on the region around the pores. The size of the pollen grains also helps to some extent, in the discrimination of the species. Therefore, it can be concluded that the genus Asystasia is eurypalynous.

3.3. POLLEN MORPHOLOGY IN ASYSTASIA GANGETICA (L.) T. ANDERS. s.l.

Figs. 11-14. Pollen grains radially symmetrical, isopolar, 3-porate, with nine colpoid streaks, pleurotreme, prolate, $56-87 \times 36-50 \mu\text{m}$ (P/E. 100 = 141-184). Pollen grains oval inequatorial view, amb triangular.

Pores (2-) $3-5 \mu\text{m}$ in diameter, circular to oval, membrane densely studded with blunt processes which become pointed towards the periphery. Each apertural region has three narrow colpoid streaks dividing the exine into three broad and six narrow strips; the central colpoid streak passes through the pore and fuses with its counterparts at the poles; the ends of the lateral colpoid streaks belonging to different apertural region fuse like arches in the polar region.

Exine $4-6 \mu\text{m}$ thick at poles, (8-) $10-15 \mu\text{m}$ thick at equator, Sexine (1-) $2 \mu\text{m}$ thick at poles, (5-) $6-8$ (-9) μm thick at equator, tectate, Tectum smooth, provided with densely spaced circular to slit-like perforations. The narrow sexinuous strips are either continuous or band-like or broken into two rarely four $\pm$ crescent or bar-like pieces at the pores. The bacula at the equatorial region are relatively long and slender, continuous or broken either suspended from the tectum or standing on the nexine, those

standing on the nexine with their ends free or in contact with the suspended bacula. At the base of the bacula there is a granular layer; the bacula in the polar region are continuous or broken shorter and stouter than those in the equatorial region.

Nexine (2-) 3-4) (-5) μm thick at poles, 4-7 μm at equator inner outline dumb-bell-shaped, straight at the equator.

The pollen grains of 56 specimens of A. gangetica (L). T. Anders. s.l. have been investigated using light (LM), scanning electron microscope (SEM) and transmission electron microscope (TEM).

Of the 56 specimens of the species, the smallest pollen grains are found in the following specimens from tropical Africa: Drummond and Hemsley 1949 (56 x 36 μm) from Kenya and Fries 3604 (58 x 37 μm) from Tanzania. The largest pollen grains among the specimens from Africa and its neighbouring islands are found in a specimen from South Africa, Nielsen 1450 (78 x 50 μm).

Among the specimens from India and other countries, the smallest pollen grains are found in Bremer et al. 190 (70 x 44 μm) from Sri Lanka and the largest in Kew 2269 (87 x 50 μm) a specimen grown in Kew Botanical Garden from seed obtained from India.

In general, the specimens from southern Africa have larger pollen grains than those from tropical Africa and the neighbouring islands. The specimens from India and other countries possess larger pollen grains than most specimens from Africa.

In all pollen grains investigated, the surface of the pollen grains have nine narrow colpoid streaks dividing the sexine into three broad and six narrow strips. The narrow sexinuous strips are continuous in many of the pollen grains (Fig. 11 A and D). However, in some pollen grains, the narrow sexinuous strips are broken on the polar sides of the pores (Fig. 11 B). Still in others the narrow sexinuous strips are broken on both the polar and the equatorial sides of the pores (Fig. 11. C).

Transmission electron microscope photographs (Fig. 14) have revealed that the bacula at the equatorial region are longer and thinner than those in the polar region. In both regions, the bacula are either continuous or broken and suspended from the tectum or standing on the nexine. The ends of the standing bacula are free or in contact with the suspended bacula. Raj (1961) described the pollen grains of this species (A. gangetica) as having reticulate sexine.

Bhaduri (1944) and Chaubal in Raj (1961) described the pollen grains as 3-colporate. But this study has revealed that the sexine is smooth, the tectum provided with perforations and the pollen grains are 3-porate.

3.4. VARIATION IN GENERAL MORPHOLOGY IN ASYSTASIA GANGETICA
(L.) T. ANDERS.

Clarke (in Thiselton-Dyer, 1899-1900) used the character of leaf shape and size, inflorescence type, bract size, calyx length, corolla length, and pubescence to separate fifteen species of Asystasia Blume. Nees in Wallich (1832) included three and in de Candolle (1847) seven varieties of A. coromandeliana Nees (= A. gangetica (L.) T. Anders. s.l.) based on the pubescence of stems and leaves and/or leaf and corolla length. In the study reported here these and other characters were studied and the materials were found to belong to two groups, one characterized by smaller flowers and a more or less yellowish corolla in dry state and the other by bigger flowers and purplish to pale-yellow corolla with reticulate conspicuous veins. The first group is designated as the African group and the second the Indo-Malayan.

Leaf shape and size: this character varies in both groups. The African group has ovate, subovate, lanceolate or rarely oblong leaves (2.5-8.0 x 1.4-4.5 cm), even up to 10.0 x 5.0 cm for Pappi 4071 from Ethiopia and 13.0 x 7.0 cm for Bullock 2321 from Tanzania. The Indo-Malayan group possesses ovate or sub-ovate leaves (1.9-6.5 x 1.5-4.0 cm). In general, the Indo-Malayan group has shorter and more ovate leaves than the African group. But this character does not show discontinuous

variation and it is not found a useful character for taxonomic discrimination (Fig. 16).

Inflorescence type: the inflorescence of both groups is a terminal raceme which tends to be much branched in the Indo-malayan group and less so in the African group. But the gap between them is bridged by some specimens from the African group which have much branched inflorescences forming a terminal panicle, similar to the former group.

Bract size: this character shows continuous variation within and between the two groups. The bracts of the African group are 0.8 to 3.0 mm long and 0.3 to 0.8 mm wide (at the base) while those of the Indo-malayan group are 1.0 to 2.0 mm long and 0.4 to 0.8 mm wide.

Calyx length: this character also shows continuous variation. The calyx length of the African group varies from 4.0 to 7.5 mm whereas that of the Indo-malayan group varies from 4.5 to 10.0 mm. Although the latter group tends to have a longer calyx than the former, this character has not been found taxonomically useful (Fig. 17).

The two quantitative characters that show a more or less discontinuous variation are corolla length and style and stigma length (Fig. 18 and 19, respectively). The distribution of these characters are shown in a scatter diagram (Fig. 20).

Almost all specimens from the African group have corolla of less than 25 mm whereas almost all specimens from the Indo-malayan group have corolla of 25 mm and above in length.

Among the African group, specimens from South Africa: Fries 3596 and 3597, Larsen 21 and Nielsen 1450 have corolla length of 24.7 mm, 25.0 mm, 25.0 mm and 26.0 mm, respectively. However, one other specimen from South Africa, Wood 1006, has corolla length of 20.0 mm while all specimens of the tropical African group have corolla less than 25.0 mm long. Thus, the specimens from South Africa except the last one have their corolla intermediate between the two groups.

A few specimens in the Indo-Malayan group also deviate in their range of corolla length from that for the group as a whole. The specimen from Biaro Island, Nielsen 795 and a specimen from Sri Lanka, Wanntorp 2587, have corolla of 20.0 mm and 25.0 mm, respectively.

All specimens of the African group have a style and stigma less than 15.0 mm long. Almost all specimens of the Indo-Malayan group possess style and stigma of more than 15.0 mm long. But a few specimens, the one from Biaro Island, Nielsen 795, one from Florida, Brumbach 6638 and the rest from Sri Lanka (three of the four) have style and stigma length of less than 15.0 mm.

There is a marked tendency for specimens from Biaro Island and Sri Lanka to deviate from the Indo-Malayan group. The specimen from Biaro Island has the shortest corolla and style and stigma among the Indo-Malayan group. Its style and stigma are even shorter than the shortest style and stigma in the African group. Although the specimens studied from Sri Lanka are only four, the placing of these specimens in the Indo-Malayan group is doubted due to few reasons. Except one specimen, the rest have the shortest corolla among their members besides the specimen from Biaro Island. These specimens also have the shortest style and stigma length apart from the specimens from Biaro Island and Florida.

The South African specimens deviate from the tropical African group in their longer corolla and relatively longer style and stigma. The South African populations of the group could probably have been introduced to South African from India and/or other centres of the Indo-Malayan group. But these populations also deviate from the Indo-Malayan group by their shorter corolla and style and stigma lengths. Until further studies are done on more material from the region, the specimens from South Africa should be kept in the African group.

Other characters: the variation in pollen size (Figs. 21, 22 and 23) supports the distinction between the two groups revealed by the variation in corolla and style and stigma lengths. But since the distinction in the pollen size is not very sharp, its taxonomic usefulness is limited.

The length of the capsules shows continuous variation from 18.0 to 28.0 mm in the African group and 21.0 to 31.0 mm in the Indo-Malayan group. The capsules of the majority of the specimens of the African group are less than 25.0 mm long whereas those of the majority of the other group are more than 25.0 mm. But the usefulness of this character is limited by its continuous variation.

Seed morphology seems to be the most important qualitative character. In the African group the larger part of the surface is covered by almost confluent processes of more or less equal size, whereas in the Indo-Malayan group the processes are of unequal size and relatively isolated from each other (Fig. 15). In the African group the margin of the seed is more or less undulate to slightly crenate while in the Indo-Malayan group it is double dentate. Moreover, the seeds of the African group are smaller (4-5 mm in diameter) than the Indo-Malayan group (5-5.5 mm in diameter). As few of the specimens had mature fruit it was not possible to make as thorough an investigation of the distribution of fruit and seed characters as it was for vegetative and floral ones.

TAXONOMIC CONCLUSION

Although the South African specimens deviate from the tropical African specimens, they are retained in the African group until further studies are performed on more material from South Africa. Similarly, the specimens from Biaro Island and Sri Lanka are kept in the Indo-Malayan group.

Specific distinction normally requires that discontinuous variation should be found in two or more independent character (Stebbins, 1950; Steenis, 1957; Bjornstad et al. 1971). Subspecific rank is the only one in which geographical distribution can be taken as a decisive character in association with a single morphological difference (Davis & Heywood, 1963). Although the two groups are separated mainly by the corolla and style and stigma lengths, these features are not considered independent characters since as Hedberg (1957) states a larger corolla tends to be associated with a larger style. Accordingly, the rank of subspecies is given to the two groups.

The African group is given the name used by Nees (1847) for a variety raised to subspecies micrantha. The varietal epithet micrantha is selected because it defines the small-flowered African group. Furthermore, Nees described this

variety as having a corolla about half the length of that in his variety alpha (based on material from India). The type specimen (microfiche photograph seen) is also a good representative of the African group, and was collected from the Sudan.

SYNOPSIS TO THE TAXA TREATED AND SPECIMENS SEEN

KEY TO THE SUBSPECIES

Corolla normally more than 25.0 mm long; style

and stigma normally more than 15.0 mm long....subsp.

gangetica

Corolla normally less than 25.0 mm

long; style and stigma less than

15.0 mm long.....subsp. micrantha

Asystasia gangetica (L.) T. Anders. (1864) subsp. gangetica.

Justicia gangetica L., Amoen. Acad. 4: 299-300 (1759).

Orig. coll.: There are two specimens in the Linnaean

Herbarium, nos. 28.27 and 28.28 (seen on microfiche

only).

DESCRIPTION

Perennial suffrutescent herb with trailing woody stem,
rarely suberect 0.7 to 2.0 m long. Stem branched, sub-
quadrangular or quadrangular, pubescent or nearly glabrous
except at nodes. Leaves ovate or subovate; base cordate,
truncate, round or cuneate; apex acute, mucronate,

truncate or rarely apiculate; sparsely pubescent or nearly glabrous; upper and/or lower surface covered with + densely spaced bar-like cystoliths; lateral veins 4 to 6 pairs; petiole (2.0 -) 5.0 - 30.0 (-54.0) mm long. Inflorescence a terminal raceme, lax; peduncles 2.0 to 25.0 cm long; flowers one-sided, alternate rarely opposite, pubescent or nearly glabrous; pedicels 1.5 to 3.0 mm long, pubescent with glandular and eglandular hairs. Bracts and bracteoles minute, 1.0 to 2.0 mm long; base 0.4 to 0.8 mm wide + glabrous, triangular, margin ciliate; apex acuminate rarely acute. Calyx 4.5 to 10.0 mm long, lobes 0.8 to 1.5 mm wide at base, + equal, linear lanceolate, apex acuminate; sparsely pubescent with glandular and eglandular hairs, glandular hairs dominating on the tube. Corolla purplish rarely yellowish or whitish with reticulate and conspicuous veins, 25.0 to 40.0 mm long rarely less; tube 21.0 to 31.0 mm long; sparsely pubescent with glandular and eglandular hairs, eglandular hairs dense below the attachment of the stamens (inside the tube). Stamens didynamous, one long and one short; longer pair 6.0 to 10.5 mm long and provided with a line of short glandular hairs (along the length); shorter pair 5.0 to 8.0 mm long + glabrous; anthers 2.0 to 4.0 mm long, cells unequally placed, tailed at the base. Ovary conical,

2.0 to 3.5 mm long; style pubescent at and near the base (about one-third of its length), 14.0 to 22.0 mm long including the stigma, rarely less; stigma slightly bifid. Capsule 21.0 to 31.0 mm long, hirsute with glandular and eglandular hairs. Seeds compressed, about 5.0 to 5.5 mm in diameter, glabrous but provided with unequal sized processes, margin double dentate, grey in colour.

DISTRIBUTION

Amboina, Barbados, Biaro, Florida, Galathea, Hawaii, India, Jamaica, Java, Malaya, New Guinea, Philippines, Sri Lanka, Thailand, Trinidad, Venezuela (Fig. 24). Also reported from British Guiana and Colombia (Leonard 1953).

HABITAT

Grassland, roadside, riverine forest and hilly grounds. The only altitudes recorded are 50 and 200 m for New Guinea and Thailand, respectively.

DESCRIPTION

Weakly scrambling suffrutescent herb, rooting at lower nodes, rarely erect, 0.25 to 2.0 m long. Stem branched, rarely simple. Leaves ovate, subovate, lanceolate or rarely oblong, 2.5 to 13.0 cm long, 1.4 to 7.0 cm wide; base cordate,

truncate, rounded or rarely oblique; apex acuminate, acute, mucronate or rarely obtuse or apiculate; petiole 3.5 to 57.0 mm long. Peduncles 1.5 to 23.0 cm long, 3-many flowered; pedicels 0.8 to 3.0 mm long. Bract 0.8 to 3.0 mm long, 0.3 to 0.8 mm wide at base. Calyx 4.0 to 7.0 mm long, lobes 0.5 to 1.5 mm wide at base. Corolla white with violet markings on the lower lip, rarely pale blue or pale mauve, dries yellow, 12.0 to 26.0 mm long, tube 8.5 to 19.0 mm long. Stamens, longer pair 3.5 to 9.0 mm long; shorter pair 2.5 to 7.0 mm long; anthers 1.5 to 3.0 mm long, rarely provided with dark-blue line dorsally. Ovary 2.0 to 4.0 mm long; style and stigma 6.0 to 14.5 mm long. Capsule 18.0 to 26.0 mm long. Seeds 4.0 to 5.0 mm in diameter provided with +equal sized processes, margin undulate or crenate.

DISTRIBUTION

Aldabra, Angola, Benin, Botswana, Burundi, Cameroon, Central Africa, Republic, Chad, Congo, Ethiopia, Gabon, Ghana, Ivory Coast, Kenya, Liberia, Madagascar, Malawi, Mozambique, Namibia, Nigeria, Reunion, Rwanda, Senegal, Seychelles, Sierra Leone, Socotra, South Africa, Sudan, Tanzania, Togo, Uganda, Yemen Arab Republic, Zaire, Zambia, Zimbabwe (Fig. 24). Also reported from Boror, equatorial Guinea, Macias Nguema Biyoga, Niger, Rrincipe,

Sao Tome and Swaziland (Compton, 1976; Exell, 1944;
Bentham, in Hooker, 1849).

HABITAT:

Generally disturbed habitats such as roadsides, forest
clearing and old farm lands and all soil types. 0-2200 m
(reported from 3100 m in Kenya).

Fig. 7 A-B, *Asystasia charmian* S. Moore
 A, equatorial view, SEM micrograph (X 800);
 B, polar view, LM photograph (X 1000).

Fig. 16. Scatter diagram illustrating correlation between leaf length (vertical axis) and leaf width (horizontal axis) both in mm. Note: Bullock 2321 is not included.

Fig. 17. Histograms illustrating variation in calyx length. Vertically one line represents one collection. Horizontal scale shows class intervals for calyx length.

Fig. 18. Histogram illustrating variation in corolla length. Horizontal scale shows class intervals for corolla length. Vertically one line represents one collection

Fig. 19. Histograms illustrating variation in style and stigma length. Horizontal scale shows class intervals for style and stigma length. Vertical all one line represents one collection.

▲ = subsp. gangetica

⊙ = specimens from Biaro and Sri Lanka

● = subsp. micrantha

○ = specimens from S. Africa

Fig. 20. Scatter diagram illustrating correlation between corolla length (vertical axis) and style and stigma length (horizontal axis). Measurements in mm.

Fig. 21. Histograms illustrating variation in polar axis. Horizontal scale shows class intervals for polar axis. Vertically one line represents one collection.

Fig. 22. Histograms illustrating variation in pollen size (Equatorial diameter). Vertically one line represents one collection. Horizontal scale shows class intervals for equatorial diameter.

▲ = subsp. gangetica
● = subsp. micrantha

Fig. 23. Scatter diagram illustrating correlation between Equatorial diameter (horizontal axis) and polar axis (vertical axis). Measurements are in μm .

Fig. 24. Map showing known geographical distribution of *Asystasia gangetica* (L.) T. Anders. subsp. *gangetica* (black triangles) and subsp. *micrantha* (black dots).

Scale. 1:150,000,000.
